

Instantaneous solar container equation of capacitor element

Overview

The energy density is calculated as: $ED = E/V$ or E/m With : $ED =$ the energy density in joules per cubic meter (J/m^3) or joules per kilogram (J/kg). According to the derivation we did in class, we were getting: $P = -V_{rms} I_{rms} \sin 2\omega t$ for pure inductive circuit because we took $I = I_m \sin(\omega t - \pi/2)$ and $V = V_m \sin \omega t$ I understand the basic idea; current lags behind applied voltage by 90 degree in inductive and the opposite happens in capacitive. Thus, the capacitor voltage is depends on the past history of the capacitor current - has memory.
