

# Machinery for pumped storage power stations

## Overview

---

Open-loop pumped storage hydropower systems connect a reservoir to a naturally flowing water feature via a tunnel, using a turbine/pump and generator/motor to move water and create electricity. The main difference between the two being that water just flows from a high point to a low point in a hydroelectric plant, but the water in a pump storage power station. Hydroelectric power plants also play an important role in water resource management, flood control, navigation, irrigation and in creating recreation areas. In order to fulfil the power system control, PHS can switch within seconds for synchronous motor-generators. The so called doubly feed induction machines (DFIM) increase the flexibility particularly during pumping mode.
